Chapter 1

Determinant

1.1 Calculation Techniques

Example 1.1.1

$$D_n = \begin{vmatrix} x & a & \cdots & a \\ a & x & \cdots & a \\ \vdots & \vdots & \ddots & \vdots \\ a & a & \cdots & x \end{vmatrix} = (x + (n-1)a)(x-a)^{n-1}.$$

Proof. Upper triangularization. There are two possible ways to achieve this.

1. Multiple subtraction. Subtract row 1 from row 2, row 3, \dots , row n to get a shape like

and then eliminate the first column.

$$D_{n} = \begin{vmatrix} x & a & \cdots & a \\ a & x & \cdots & a \\ \vdots & \vdots & \ddots & \vdots \\ a & a & \cdots & x \end{vmatrix} = \begin{vmatrix} x & a & \cdots & a \\ a - x & x - a \\ \vdots & \vdots & \ddots \\ a - x & x - a \end{vmatrix}$$

$$\frac{c_{1} + = c_{2} + \cdots + c_{n}}{} \begin{vmatrix} x + (n-1)a & a & \cdots & a \\ x - a & \vdots & \ddots & \vdots \\ a - x & x - a & \vdots & \vdots & \ddots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ x - a & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots &$$

2. Accumulation. Add row 2, row 3, ..., row n to row 1.

$$D_{n} = \begin{vmatrix} x & a & \cdots & a \\ a & x & \cdots & a \\ \vdots & \vdots & \ddots & \vdots \\ a & a & \cdots & x \end{vmatrix} = \frac{\mathbf{r}_{1} + = \mathbf{r}_{2} + \cdots + \mathbf{r}_{n}}{\mathbf{r}_{1} + = \mathbf{r}_{2} + \cdots + \mathbf{r}_{n}} \begin{vmatrix} x + (n-1)a & x + (n-1)a & \cdots & x + (n-1)a \\ a & x & \cdots & a \\ \vdots & \vdots & \ddots & \vdots \\ a & a & \cdots & x \end{vmatrix}$$

$$= (x + (n-1)a) \begin{vmatrix} 1 & 1 & \cdots & 1 \\ a & x & \cdots & a \\ \vdots & \vdots & \ddots & \vdots \\ a & a & \cdots & x \end{vmatrix}$$

$$= \frac{\mathbf{r}_{2} - = a * \mathbf{r}_{1}}{\mathbf{r}_{n} - = a * \mathbf{r}_{1}} (x + (n-1)a) \begin{vmatrix} 1 & 1 & \cdots & 1 \\ x - a & & & \\ & \ddots & & & \\ & & x - a \end{vmatrix}.$$

Example 1.1.2 Suppose $x_i \neq a_i \ (i = 1, 2, \dots, n)$.

$$D_n = \begin{vmatrix} x_1 & a_2 & \cdots & a_n \\ a_1 & x_2 & \cdots & a_n \\ \vdots & \vdots & \ddots & \vdots \\ a_1 & a_2 & \cdots & x_n \end{vmatrix} = \left(1 + \sum_{i=1}^n \frac{a_i}{x_i - a_i}\right) \prod_{i=1}^n (x_i - a_i).$$

Proof. Increase order. Consider

Then we can use the multiple subtraction method in Example 1.1.1 to get an upper triangular determinant.

Example 1.1.3 Suppose $a \neq b$.

$$D_n = \begin{vmatrix} x & a & \cdots & a \\ b & x & \cdots & a \\ \vdots & \vdots & \ddots & \vdots \\ b & b & \cdots & x \end{vmatrix} = \frac{a(x-b)^n - b(x-a)^n}{a-b}.$$

Proof. Recurrence. By splitting the first column we get

Transpose it to obtain another recurrence relation

$$D_n = D_n^T = b(x-a)^{n-1} + (x-b)D_{n-1}.$$

Solve D_n from the two recurrence equations.

Chapter 2

Matrix

2.1 Properties

Proposition 2.1.1 (properties of square matrices) Let A, B be $n \times n$ matrices.

1. If A, B is invertible,

$$(AB)^{-1} = B^{-1}A^{-1}, \quad (kA)^{-1} = \frac{1}{k}A^{-1}(k \neq 0), \quad |A^n| = |A|^n \ (n \in \mathbb{Z}).$$

2.

$$(AB)^{\mathrm{T}} = B^{\mathrm{T}}A^{\mathrm{T}}, \quad (kA)^{\mathrm{T}} = kA^{\mathrm{T}}, \quad |A^{\mathrm{T}}| = |A|, (A+B)^{\mathrm{T}} = A^{\mathrm{T}} + B^{\mathrm{T}}.$$

3.

$$\operatorname{adj}(AB) = \operatorname{adj}(B)\operatorname{adj}(A), \quad \operatorname{adj}(kA) = k^{n-1}\operatorname{adj}(A), \quad |\operatorname{adj}(A)| = |A|^{n-1}, \quad \operatorname{adj}(\operatorname{adj}(A)) = |A|^{n-2}A.$$

4. The mappings $^{-1}$, $^{\mathrm{T}}$, adj are commutable.

Proposition 2.1.2 (properties of block matrices) Suppose $A = (A_{ij})$.

1.

$$A^{\mathrm{T}} = (A_{ji}^{\mathrm{T}}).$$

2. If A, B is invertible,

$$\begin{pmatrix} 0 & A \\ B & 0 \end{pmatrix}^{-1} = \begin{pmatrix} 0 & B^{-1} \\ A^{-1} & 0 \end{pmatrix}$$

Proposition 2.1.3 (properties of block diagonal matrices) Suppose $A = \text{diag}(A_1, A_2, \dots, A_n)$, $A_i (i = 1, 2, \dots, n)$ are square matrices.

1.

$$\operatorname{diag}(A_1, A_2, \cdots, A_n)^k = \operatorname{diag}(A_1^k, A_2^k, \cdots, A_n^k) \quad (k \in \mathbb{Z}_{\geq 0}).$$

Furthermore, if $A_i (i = 1, 2, \dots, n)$ are invertible,

$$\operatorname{diag}(A_1, A_2, \cdots, A_n)^k = \operatorname{diag}(A_1^k, A_2^k, \cdots, A_n^k) \quad (k \in \mathbb{Z}).$$

2.

$$|\operatorname{diag}(A_1, A_2, \cdots, A_n)| = |A_1| |A_n| \cdots |A_n|$$
.

2.2 Linear Equations

2.2.1 Homogeneous Linear Equations

Let $A_{m \times n} = (\alpha_1, \alpha_2, \dots, \alpha_n) \in M_{m,n}(F)$. There are two possible solution sets for the equation Ax = 0.

- 1. Ax = 0 has unique solution x = 0.
- 2. Ax = 0 has infinitely many solutions.

Rank

- 1. Ax = 0 has unique solution $x = 0 \iff r(A) = n$.
- 2. Ax = 0 has infinitely many solutions $\iff r(A) < n$.

Row Echelon Form

Suppose A is equivalent to the following row echelon form

$$\begin{pmatrix} 1 & * & \cdots & * & * & \cdots & * & * & * & \cdots & * \\ 1 & * & \cdots & * & * & * & * & \cdots & * \\ & & & \ddots & \vdots & \vdots & \ddots & \vdots \\ & & & & 1 & * & \cdots & * \\ & & & & 0_{(m-r)\times n} \end{pmatrix}.$$

r denotes the number of the nonzero rows.

- 1. Ax = 0 has unique solution $x = 0 \iff r = n$.
- 2. Ax = 0 has infinitely many solutions $\iff r < n$.

Spanned Space of Column Vectors

If we see A as $(\alpha_1, \alpha_2, \dots, \alpha_n)$, where $\alpha_j \in F^m$ $(j = 1, 2 \dots, n)$, then

$$Ax = 0 \iff x_1\alpha_1 + x_2\alpha_2 + \dots + x_n\alpha_n = 0.$$

- 1. Ax = 0 has unique solution $x = 0 \iff \alpha_1, \alpha_2, \dots, \alpha_n$ are linearly independent \iff dim span $(\alpha_1, \alpha_2, \dots, \alpha_n) = n$.
- 2. Ax = 0 has infinitely many solutions $x = 0 \iff \alpha_1, \alpha_2, \dots, \alpha_n$ are linearly dependent \iff dim span $(\alpha_1, \alpha_2, \dots, \alpha_n) < n$.

Linear Mapping

If we see A as a linear mapping $A \in \text{Hom}_{\text{Vect}_F}(F^n, F^m)$, that is

$$\mathcal{A}: F^n \longrightarrow F^m$$
$$x \longmapsto Ax,$$

then the solution space of Ax = 0 is ker \mathcal{A} . Since im $\mathcal{A} = \operatorname{span}(\alpha_1, \alpha_2, \dots, \alpha_n)$, we have

$$r(A) = \dim \operatorname{span}(\alpha_1, \alpha_2, \cdots, \alpha_n) = \dim \operatorname{im} A.$$

- 1. Ax = 0 has unique solution $x = 0 \iff A$ is injective $\iff \ker A = 0 \iff \operatorname{im} A = F^m$.
- 2. Ax = 0 has infinitely many solutions $x = 0 \iff \mathcal{A}$ is not injective $\iff \dim \ker \mathcal{A} > 0 \iff \dim \dim \mathcal{A} < n$.

Orthogonal Complement

If we see A as $(\beta_1, \beta_2, \dots, \beta_n)^T$, where $\beta_i \in F^n$ $(i = 1, 2 \dots, m)$, then

$$Ax = 0 \iff \langle \beta_i, x \rangle = \beta_i^T x = 0, (i = 1, 2 \cdots, m).$$

The solution space of Ax = 0 is

$$\bigcap_{i=1}^{m} \operatorname{span}\left(\beta_{i}^{T}\right)^{\perp}.$$

Determinant

If A is a square matrix, then

- 1. Ax = 0 has unique solution $x = 0 \iff |A| \neq 0$.
- 2. Ax = 0 has infinitely many solutions $\iff |A| = 0$.

2.2.2 Nonhomogeneous Linear Equations

Let $A_{m \times n} = (\alpha_1, \alpha_2, \dots, \alpha_n)$. There are two possible results for the equation Ax = b:

- 1. Ax = b has no solution.
- 2. Ax = b has at least one solution.
 - (a) Ax = b has a unique solution.
 - (b) Ax = b has infinitely many solutions.

Rank

- 1. Ax = b has no solution $\iff r(A \mid b) = r(A) + 1$.
- 2. Ax = b has at least one solution $\iff r(A \mid b) = r(A)$.
 - (a) Ax = b has a unique solution $\iff r(A) = n$.
 - (b) Ax = b has infinitely many solutions $\iff r(A) < n...$

Row Echelon Form

Suppose $(A \mid b)$ is equivalent to the following row echelon form

r denotes the number of the nonzero rows.

- 1. Ax = b has no solution $\iff d_{r+1} \neq 0$.
- 2. Ax = b has at least one solution $\iff d_{r+1} = 0$..
 - (a) Ax = b has a unique solution $\iff r = n$.
 - (b) Ax = b has infinitely many solutions $\iff r < n$..

Linear Mapping

If we see A as a linear mapping $A \in \operatorname{Hom}_{\mathsf{Vect}_F}(F^n, F^m)$, that is

$$\mathcal{A}: F^n \longrightarrow F^m$$
$$x \longmapsto Ax,$$

then the solution space of Ax = b is $A^{-1}(b) + \ker A$.

- 1. Ax = b has no solution $\iff b \notin \text{im } A$.
- 2. Ax = b has at least one solution $\iff b \in \text{im } A$.
 - (a) Ax = b has a unique solution $\iff \mathcal{A}$ is injective $\iff \ker \mathcal{A} = 0 \iff \operatorname{im} \mathcal{A} = F^m$.
 - (b) Ax = b has infinitely many solutions $x = 0 \iff \mathcal{A}$ is not injective \iff dim ker $\mathcal{A} > 0 \iff$ dim im $\mathcal{A} < n$.

Determinant

If A is a square matrix, then

- 1. Ax = b has unique solution $\iff |A| \neq 0$.
- 2. Ax = b has no solution or have infinitely many solutions $\iff |A| = 0$.
